Refactoring code by permuting the order of operations

- Expected properties of refactored code:

First extract user information, then convert stream to list; or first convert to list, then extract user information:

`db.getRows.toList.map(getUserInfo)` gives the same result as

`db.getRows.map(getUserInfo).toList`

First extract user information, then exclude invalid rows; or first exclude invalid rows, then extract user information:

`db.getRows.map(getUserInfo).filter(isValid)` gives the same result as

`db.getRows.filter(getUserInfo andThen isValid).map(getUserInfo)`

- These refactorings are guaranteed to be correct

Summary of the type notation

The short type notation helps in symbolic reasoning about types

Description	Scala examples	Notation
Typed value	`x: Int`	$x^{:\text{Int}}$ or $x : \text{Int}$
Unit type	`Unit`, `Nil`, `None`	$\mathbb{1}$
Type parameter	`A`	A
Product type	`(A, B)` or `case class P(x: A, y: B)`	$A \times B$
Co-product type	`Either[A, B]`	$A + B$
Function type	`A => B`	$A \rightarrow B$
Type constructor	`List[A]`	List^A
Universal quantifier	`trait P { def f[A]: Q[A] }`	$P \triangleq \forall A.\, Q^A$
Existential quantifier	`sealed trait P[A]` `case class Q[A, B]() extends P[A]`	$P^A \triangleq \exists B.\, Q^{A,B}$

Example: Scala code `def flm(f: A => Option[B]): Option[A] => Option[B]`
is denoted by flm : $(A \rightarrow \mathbb{1} + B) \rightarrow \mathbb{1} + A \rightarrow \mathbb{1} + B$

Summary of the code notation

The short code notation helps in symbolic reasoning about code

Scala examples	Notation
`()` or `true` or `"abc"` or `123`	1, true, "abc", 123
`def f[A](x: A) = ...`	$f^A(x^{:A}) \triangleq ...$
`{ (x: A) => expr }`	$x^{:A} \to \text{expr}$
`f(x)` or `x.pipe(f)` (Scala 2.13)	$f(x)$ or $x \triangleright f$
`val p: (A, B) = (a, b)`	$p^{:A \times B} \triangleq a \times b$
`{case (a, b) => expr}` or `p._1` or `p._2`	$a \times b \to \text{expr}$ or $p \triangleright \pi_1$ or $p \triangleright \pi_2$
`Left[A, B](x)` or `Right[A, B](y)`	$x^{:A} + \mathbb{0}^{:B}$ or $\mathbb{0}^{:A} + y^{:B}$

`val q: C = (p: Either[A, B]) match {`
`  case Left(x) => f(x)`
`  case Right(y) => g(y)`
`}`
	$q^{:C} \triangleq p^{:A+B} \triangleright \begin{array}{c\|\|c} & C \\ \hline A & x^{:A} \to f(x) \\ B & y^{:B} \to g(y) \end{array}$

`def f(x) = { ... f(y) ... }`	$f(x) \triangleq ... \overline{f}(y) ...$
`f andThen g` and `(f andThen g)(x)`	$f \,\overset{\circ}{,}\, g$ and $x \triangleright f \,\overset{\circ}{,}\, g$ or $x \triangleright f \triangleright g$
`p.map(f).map(g)`	$p \triangleright f^{\uparrow F} \triangleright g^{\uparrow F}$ or $p \triangleright f^{\uparrow F} \,\overset{\circ}{,}\, g^{\uparrow F}$

Refactored code: further examples

Writing the previous examples as equations:

`def toList[A]: Stream[A] => List[A]` written as $\text{toList}^A : \text{Str}^A \to \text{List}^A$

$$\begin{array}{ccc} \text{Str}^A & \xrightarrow{\text{toList}^A} & \text{List}^A \\ \downarrow f^{\uparrow\text{Str}} & & \downarrow f^{\uparrow\text{List}} \\ \text{Str}^B & \xrightarrow{\text{toList}^B} & \text{List}^B \end{array}$$

`_.toList.map(f) == _.map(f).toList`

$(f^{:A\to B})^{\uparrow\text{Str}} \,\mathring{,}\, \text{toList}^B = \text{toList}^A \,\mathring{,}\, f^{\uparrow\text{List}}$

`def filt[A]: (A => Boolean) => Stream[A] => Stream[A]`

$$\begin{array}{ccc} \text{Str}^A & \xrightarrow{\text{filt}^A(f\,\mathring{,}\,p)} & \text{Str}^A \\ \downarrow f^{\uparrow\text{Str}} & & \downarrow f^{\uparrow\text{Str}} \\ \text{Str}^B & \xrightarrow{\text{filt}^B(p)} & \text{Str}^B \end{array}$$

$\text{filt}^A : (A \to 2) \to \text{Str}^A \to \text{Str}^A$

$(f^{:A\to B})^{\uparrow\text{Str}} \,\mathring{,}\, \text{filt}^B(p^{:B\to 2}) = \text{filt}^A(f\,\mathring{,}\,p) \,\mathring{,}\, f^{\uparrow\text{Str}}$

- A transformation before `map` equals a transformation after `map`
- This is called a **naturality law**
- We expect it to hold if the code works the same way for all types

Naturality laws: equations

Naturality law for a function t is an equation involving an arbitrary function f that permutes the order of application of t and of a lifted f

$$\text{List}^A \xrightarrow{\text{headOpt}^A} \text{Opt}^A \qquad \texttt{list.map(f).headOption == list.headOption.map(f)}$$

$$\downarrow f^{\uparrow\text{List}} \qquad f^{\uparrow\text{Opt}} \downarrow \qquad (f^{:A\to B})^{\uparrow\text{List}} \,\mathring{\varsigma}\, \text{headOpt} = \text{headOpt} \,\mathring{\varsigma}\, (f^{:A\to B})^{\uparrow\text{Opt}}$$

$$\text{List}^B \xrightarrow{\text{headOpt}^B} \text{Opt}^B$$

- Lifting f before t equals to lifting f after t
- Intuition: t rearranges data in a collection, not looking at values

Further examples:

- Reversing a list; $\text{reverse}^A : \text{List}^A \to \text{List}^A$

$$\texttt{list.map(f).reverse == list.reverse.map(f)}$$
$$(f^{:A\to B})^{\uparrow\text{List}} \,\mathring{\varsigma}\, \text{reverse}^B = \text{reverse}^A \,\mathring{\varsigma}\, (f^{:A\to B})^{\uparrow\text{List}}$$

- The `pure` method, `pure[A]: A => L[A]`. Notation: $\text{pu}_L : A \to L^A$

$$\texttt{pure(x).map(f) == pure(f(x))}$$
$$\text{pu}^A \,\mathring{\varsigma}\, (f^{:A\to B})^{\uparrow L} = f \,\mathring{\varsigma}\, \text{pu}^B$$

Resoning with naturality: Simplifying the `pure` method

The naturality law of `pure` for a functor L:

$$
\begin{array}{ccc}
A & \xrightarrow{\text{pu}_L} & L^A \\
\downarrow{\scriptstyle f} & & \downarrow{\scriptstyle f^{\uparrow L}} \\
B & \xrightarrow{\text{pu}_L} & L^B
\end{array}
$$

`pure(a).map(f) == pure(f(a))`

$$\text{pu}_L \,\mathring{\varsigma}\, f^{\uparrow L} = f \,\mathring{\varsigma}\, \text{pu}_L$$

Fix a value $b^{:B}$ and set $A = \mathbb{1}$ and $f \triangleq 1 \to b$ in the naturality law:

$$
\begin{array}{ccc}
\mathbb{1} & \xrightarrow{\text{pu}_L} & L^{\mathbb{1}} \\
\downarrow{\scriptstyle 1 \to b} & & \downarrow{\scriptstyle (1 \to b)^{\uparrow L}} \\
B & \xrightarrow{\text{pu}_L} & L^B
\end{array}
$$

`pure(()).map(_ => b) == pure(b)`

$$\text{pu}_L \,\mathring{\varsigma}\, (1 \to b)^{\uparrow L} = (1 \to b) \,\mathring{\varsigma}\, \text{pu}_L$$

We have expressed `pure(b)` via a constant value `pure(())` of type `L[Unit]`
The naturality law of `pure` makes it equivalent to a "wrapped unit" value
This simplifies the definition of a `Pointed` typeclass:

```
abstract class Pointed[L[_]: Functor] { def wu: L[Unit] }
```

Examples: for `Option`, `wu = Some(())`. For `List`, `wu = List(())`

Naturality laws in typeclasses

Another use of naturality laws is when implementing typeclasses

- Typeclasses require type constructors with methods `map`, `filter`, `fold`, `flatMap`, `pure`, and others

To be useful for programming, the methods must satisfy certain laws

- `map`: identity, composition
- `filter`: identity, composition, partial function, naturality
- `fold` (traverse): identity, composition, naturality
- `flatMap`: identity, associativity, naturality
- `pure`: naturality

We need to check the laws when implementing new typeclass instances
Usually, typeclass instances are written in fully parametric code

Fully parametric code: example

Fully parametric code: "works in the same way for all types"

- Example of a fully parametric function:
  ```
  def headOpt[A]: List[A] => Option[A] = {
    case Nil => None
    case head :: tail => Some(head)
  }
  ```
- The code does not use explicit types
- The same code in the matrix notation:

$$\text{headOpt}^{:\text{List}^A \to \mathbb{1}+A} \triangleq \begin{array}{c|c|c} & \mathbb{1} & A \\ \hline \mathbb{1} & \text{id} & \mathbb{0} \\ A \times \text{List}^A & \mathbb{0} & h \times t \to h \end{array}$$

  where $\text{List}^A \triangleq \mathbb{1} + A \times \text{List}^A$ is a recursively defined type constructor:
  ```
  final case class List[A](x: Option[(A, List[A]])
  ```

Naturality laws express the programmer's intuition about the properties of fully parametric code

Example of code that is *not* fully parametric:

- An implementation of `headOpt` that has special code for `Int` type

```scala
def headOptBad[A]: List[A] => Option[A] = {
  case Nil                => None
  case (head: Int) :: tail   => Some((head + 100).asInstanceOf[A])
  case head :: tail       => Some(head)
}
```

- The code uses explicit run-time type detection

The function `headOptBad` fails the naturality law:

```scala
scala> headOptBad(List(1, 2, 3).map(x => s"value = $x"))
res0: Option[String] = Some(value = 1)

scala> headOptBad(List(1, 2, 3)).map(x => s"value = $x")
res1: Option[String] = Some(value = 101)
```

Full parametricity: The price we pay for "free theorems"

Free theorems only apply to **fully parametric** code:

- All argument types are combinations of type parameters
- All type parameters are treated as unknown, arbitrary types
- No hard-coded values of specific types (`123: Int` or `"abc": String`)
- No side effects (printing, `var x`, mutating values, writing files, networking, starting or stopping new threads, GUI events, etc.)
- No `null`, no `throw`ing of exceptions, no run-time type comparison
- No run-time code loading, no external libraries with unknown code

"Fully parametric" is a stronger restriction than "purely functional" (referentially transparent)

Purely functional code is fully parametric if restricted to using only `Unit` type or type parameters

- No hard-coded values of specific types, and no run-time type detection

Fully parametric programs are written using the 9 code constructions:

```
def fmap[A, B](f: A => B): List[(A, A)] => List[(B, B)] = { // 3
   case Nil            => Nil
// 8   1                  1,7
   case head :: tail   => (f (head._1), f (head._2)) :: fmap(f)(tail)
// 8         6              2 4    6 5 2 4    6    7 9
}        // This code has used each of the nine allowed constructions.
```

1. Use `Unit` value (or a "named `Unit`"), e.g. `()`, `Nil`, or `None`. Notation: 1

2. Use bound variable (a given argument of the function). Notation: x

3. Create function: `{ x => expr(x) }`. Notation: $x \rightarrow \text{expr}(x)$

4. Use function: `f(x)`. Notation: $f(x)$ or $x \triangleright f$

5. Create tuple: `(a, b)`. Notation: $a \times b$

6. Use tuple: `p._1`. Notation: $\nabla_1 p$ or $p \triangleright \nabla_1$

7. Create disjunctive value: `Left[A, B](x)`. Notation: $x^{:A} + 0^{:B}$

8. Use disjunctive value: `{ case ... }` (pattern-matching); matrix code

9. Use recursive call: `fmap(f)(tail)`. Notation: $\overline{\text{fmap}_{\text{List}}}(f)(t)$

Naturality laws and parametricity

- The **parametricity theorem** guarantees that all naturality laws hold as long as the method's code is fully parametric
- This saves us time: *no need* to check the naturality laws

Using the parametricity theorem is difficult

- The "theorems for free" (Reynolds; Wadler) approach needs to replace functions (one-to-one or many-to-one) by "relations" (many-to-many)
  - Derive a law with relation variables, then replace them by functions
- Alternative approach: analysis of dinatural transformations derives the naturality laws directly (Bainbridge et al.; Backhouse; de Lataillade)
  - See also a 2019 paper by Voigtländer
- Plan:
  - Start with natural transformations
  - Introduce profunctors and dinatural transformations
  - Commutativity laws for bifunctors and profunctors
  - Derive the naturality laws for dinatural transformations
  - Uniqueness of functor typeclass instances

Natural transformations and their laws

A **natural transformation** is a function t with type signature $F^A \to G^A$ that satisfies the naturality law $f^{\uparrow F} \mathbin{\text{\semicolon}} t = t \mathbin{\text{\semicolon}} f^{\uparrow G}$. Notation $t : F \rightsquigarrow G$

- Many standard methods have the form of a natural transformation
  - Examples: `headOption`, `lastOption`, `reverse`, `swap`, `map`, `flatMap`, `pure`
- If there are several type parameters, use one at a time:
  - For `flatMap`, denote flm $: (A \to M^B) \to M^A \to M^B$, fix A
    - flm $: F^B \to G^B$ where $F^B \triangleq A \to M^B$ and $G^B \triangleq M^A \to M^B$
  - The naturality law $f^{\uparrow F} \mathbin{\text{\semicolon}} \text{flm} = \text{flm} \mathbin{\text{\semicolon}} f^{\uparrow G}$ then gives the equation

$$\text{flm}\,(p^{:A \to M^B} \mathbin{\text{\semicolon}} f^{\uparrow M}) = \text{flm}\,(p^{:A \to M^B}) \mathbin{\text{\semicolon}} f^{\uparrow M}$$

The naturality law for $t^A : F^A \to G^A$ when F^A, G^A are contrafunctors:

$$
\begin{array}{ccc}
F^A & \xrightarrow{\;t^A\;} & G^A \\
\downarrow{\scriptstyle (f^{:B \to A})^{\downarrow F}} & & \downarrow{\scriptstyle f^{\downarrow G}} \\
F^B & \xrightarrow{\;t^B\;} & G^B
\end{array}
\qquad\qquad
f^{\downarrow F} \mathbin{\text{\semicolon}} t = t \mathbin{\text{\semicolon}} f^{\downarrow G}
$$

Mnemonic rule: if $t : F \rightsquigarrow G$ then the lifting to F is on the left, the lifting to G is on the right

Dinatural transformations and profunctors

Some methods do *not* have the type signature of the form $F^A \to G^A$

- `find[A]: (A => Boolean) => List[A] => Option[A]`
- `fold[A, B]: List[A] => B => (A => B => B) => B` with respect to `B`
  - The type parameter is in contravariant and covariant positions at once
  - This gives us neither a functor nor a contrafunctor
- Solution: use a profunctor $P^{X,Y}$ (contravariant in X, covariant in Y) with equal type parameters: $P^{A,A}$

A **dinatural transformation** is a function t with type signature $P^{A,A} \to Q^{A,A}$ that satisfies the naturality law $f^{\downarrow P} \,\stackrel{\circ}{,}\, t \,\stackrel{\circ}{,}\, f^{\uparrow Q} = f^{\uparrow P} \,\stackrel{\circ}{,}\, t \,\stackrel{\circ}{,}\, f^{\downarrow Q}$ where $P^{X,Y}$ and $Q^{X,Y}$ are suitable profunctors

- *All pure functions* have the type signature of a dinatural transformation
- *All* naturality laws (also for `find`, `fold`) are derived in this way
- The corresponding naturality law is guaranteed by parametricity
- Proof of parametricity theorem is a direct proof that any pure function t satisfies its law, by induction on the code structure of t
- The proof depends on the profunctor commutativity law and on the "standard" lifting codes for $f^{\uparrow P}$ and $f^{\downarrow P}$

Type constructors with two type parameters
In particular: bifunctors and profunctors

- In Scala syntax: `L[A, B]`. Example: `type L[A, B] = Either[(A, B), B]`
- In the type notation: $L^{A,B}$. Example: $L^{A,B} \triangleq A \times B + B$
- If a type constructor is fully parametric, its type parameters will be either in covariant or in contravariant positions
- **Bifunctors**: both type parameters are always in covariant positions
  - Example: `type L[A, B] = Either[(A, B), B]` is a bifunctor
  - Method `bimap[A, B, C, D](f: A => C)(g: B => D): L[A, B] => L[C, D]`
  - Laws: identity and composition for `bimap`
- **Profunctors**: one type parameter contravariant, the other covariant
  - Example: `type P[X, Y] = Option[X] => (Y, Y)` or $P^{X,Y} \triangleq \mathbb{1} + X \rightarrow Y \times Y$
  - Method `xmap[A, B, C, D](f: C => A)(g: B => D): P[A, B] => P[C, D]`
  - Laws: identity and composition for `xmap`
- If `L[A, B]` is a functor separately in `A` and `B`, is it a bifunctor?
- If `P[A, B]` is contravariant in `A` and covariant in `B`, is it a profunctor?
- They are — as long as all liftings in `A` commute with liftings in `B`
  - These are the "commutativity laws" of bifunctors and profunctors

Applying `map` to bifunctors and profunctors

The `map` method can be applied with respect to only one type parameter

- In a bifunctor `L[A, B]`, fix `B`. Denote the resulting functor by $L^{\bullet,B}$
  - In the Scala syntax with "kind projector": `L[?, B]`
  - Lifting a function $f^{:U \to V}$ is denoted by $f^{\uparrow L^{\bullet,B}} : L^{U,B} \to L^{V,B}$
  - If fixing `A` instead, a lifting is denoted by $f^{\uparrow L^{A,\bullet}} : L^{A,U} \to L^{A,V}$
  - **Commutativity law** for bifunctors: $f^{\uparrow L^{\bullet,B}} \mathbin{\raise.2ex\hbox{$_\S$}} (g^{:B \to C})^{\uparrow L^{V,\bullet}} = g^{\uparrow L^{U,\bullet}} \mathbin{\raise.2ex\hbox{$_\S$}} f^{\uparrow L^{\bullet,C}}$
- In a profunctor `P[A, B]`, fix `B`. The resulting *contrafunctor* is $P^{\bullet,B}$
  - Lifting a function $f^{:U \to V}$ is denoted by $f^{\downarrow P^{\bullet,B}} : P^{V,B} \to P^{U,B}$
  - If fixing `A` instead, a lifting is denoted by $f^{\uparrow P^{A,\bullet}} : P^{A,U} \to P^{A,V}$
    - ★ For brevity, we may denote these liftings by $f^{\downarrow P}$ and $f^{\uparrow P}$ unambiguously
  - **Commutativity law** for profunctors: $f^{\downarrow P} \mathbin{\raise.2ex\hbox{$_\S$}} g^{\uparrow P} = g^{\uparrow P} \mathbin{\raise.2ex\hbox{$_\S$}} f^{\downarrow P}$

$$
\begin{array}{ccc}
P^{A,B} & \xrightarrow{\;(f^{:C \to A})^{\downarrow P}\;} & P^{C,B} \\
\scriptstyle (g^{:B \to D})^{\uparrow P} \big\downarrow & & \big\downarrow \scriptstyle (g^{:B \to D})^{\uparrow P} \\
P^{A,D} & \xrightarrow{\;(f^{:C \to A})^{\downarrow P}\;} & P^{C,D}
\end{array}
$$

- Commutativity laws hold for *all* fully parametric type constructors
  - It is not necessary to verify the bifunctor and profunctor laws!
- Proof is by induction on the type structure of $P^{X,Y}$

Proof of the composition law of xmap

If $P^{A,B}$ is a functor in a and a contrafunctor in B, define xmap by:

$$P^{A,B} \xrightarrow{\quad (f^{:C \to A})^{\downarrow P} \quad} P^{C,B}$$

$$g^{\uparrow P} \Big\downarrow$$

$$\text{xmap}(f)(g) \triangleq \searrow P^{C,D}$$

$$\text{xmap}\left(f^{:C \to A}\right)\left(g^{:B \to D}\right) \triangleq f^{\downarrow P} \,\overset{\circ}{,}\, g^{\uparrow P}$$

The xmap composition law:

$$\text{xmap}\left(f_1\right)\left(g_1\right) \,\overset{\circ}{,}\, \text{xmap}\left(f_2\right)\left(g_2\right) = \text{xmap}\left(f_2 \,\overset{\circ}{,}\, f_1\right)\left(g_1 \,\overset{\circ}{,}\, g_2\right)$$

Proof uses the commutativity law, $f^{\downarrow P} \,\overset{\circ}{,}\, g^{\uparrow P} = g^{\uparrow P} \,\overset{\circ}{,}\, f^{\downarrow P}$, for f_2 and g_1:

$$\text{xmap}\left(f_1\right)\left(g_1\right) \,\overset{\circ}{,}\, \text{xmap}\left(f_2\right)\left(g_2\right) = f_1^{\downarrow P} \,\overset{\circ}{,}\, \underline{g_1^{\uparrow P} \,\overset{\circ}{,}\, f_2^{\downarrow P}} \,\overset{\circ}{,}\, g_2^{\uparrow P}$$

$$= \underline{f_1^{\downarrow P} \,\overset{\circ}{,}\, f_2^{\downarrow P}} \,\overset{\circ}{,}\, \underline{g_1^{\uparrow P} \,\overset{\circ}{,}\, g_2^{\uparrow P}} = \left(f_2 \,\overset{\circ}{,}\, f_1\right)^{\downarrow P} \,\overset{\circ}{,}\, \left(g_1 \,\overset{\circ}{,}\, g_2\right)^{\uparrow P}$$

$$= \text{xmap}\left(f_2 \,\overset{\circ}{,}\, f_1\right)\left(g_1 \,\overset{\circ}{,}\, g_2\right)$$

# The naturality law for dinatural transformations

Given two profunctors $P^{X,Y}$ and $Q^{X,Y}$ and a function $t^A : P^{A,A} \to Q^{A,A}$
The naturality law is an equation for functions $P^{B,A} \to Q^{A,B}$:

$$f^{\downarrow P^{\bullet,A}} \,\mathbin{;}\, t^A \,\mathbin{;}\, f^{\uparrow Q^{A,\bullet}} \overset{!}{=} f^{\uparrow P^{B,\bullet}} \,\mathbin{;}\, t^B \,\mathbin{;}\, f^{\downarrow Q^{\bullet,B}}$$

Both sides must give the same result when applied to arbitrary $p : P^{B,A}$

This law reduces to natural transformation laws when P and Q are functors
or contrafunctors

Example: writing the naturality law for `filter`

`def filter[A]: (A => Boolean) => F[A] => F[A]` for a filterable functor F

Notation: $\mathrm{filt}^A : (A \to 2) \to F^A \to F^A$ (the type `Boolean` is $2 = 1 + 1$)

Rewrite in the form of a dinatural transformation:

$$\mathrm{filt}^A : P^{A,A} \to Q^{A,A} \quad , \quad P^{X,Y} \triangleq X \to 2 \quad , \quad Q^{X,Y} \triangleq F^X \to F^Y$$

Write the code for the liftings using the specific types of P and Q:

$$(f^{:A\to B})^{\downarrow P^{\bullet,A}} = p^{:B\to 2} \to f \mathbin{\raise1pt{\tiny\S}} p \quad , \qquad f^{\uparrow P^{B,\bullet}} = \mathrm{id} \quad ,$$
$$(f^{:A\to B})^{\downarrow Q^{\bullet,B}} = q^{:F^B\to F^B} \to f^{\uparrow F} \mathbin{\raise1pt{\tiny\S}} q \quad , \qquad f^{\uparrow Q^{A,\bullet}} = q^{:F^A\to F^A} \to q \mathbin{\raise1pt{\tiny\S}} f^{\uparrow F} \quad .$$

Rewrite the naturality law $f^{\downarrow P^{\bullet,A}} \mathbin{\raise1pt{\tiny\S}} \mathrm{filt}^A \mathbin{\raise1pt{\tiny\S}} f^{\uparrow Q^{A,\bullet}} \overset{!}{=} f^{\uparrow P^{B,\bullet}} \mathbin{\raise1pt{\tiny\S}} \mathrm{filt}^B \mathbin{\raise1pt{\tiny\S}} f^{\downarrow Q^{\bullet,B}}$ as

$$(p \to f \mathbin{\raise1pt{\tiny\S}} p) \mathbin{\raise1pt{\tiny\S}} \mathrm{filt} \mathbin{\raise1pt{\tiny\S}} (q \to q \mathbin{\raise1pt{\tiny\S}} f^{\uparrow F}) \overset{!}{=} \mathrm{id} \mathbin{\raise1pt{\tiny\S}} \mathrm{filt} \mathbin{\raise1pt{\tiny\S}} (q \to f^{\uparrow F} \mathbin{\raise1pt{\tiny\S}} q) \quad .$$

To simplify this equation, apply both sides to an arbitrary value $p^{:P^{B,A}}$

Evaluate the results and obtain the naturality law of `filter`,

$$\mathrm{filt}\,(f \mathbin{\raise1pt{\tiny\S}} p) \mathbin{\raise1pt{\tiny\S}} f^{\uparrow F} \overset{!}{=} f^{\uparrow F} \mathbin{\raise1pt{\tiny\S}} \mathrm{filt}\,(p)$$

Uniqueness of functor implementations

Consequences of the parametricity theorem:

Statement 1: For any fully parametric type constructor F^A covariant in A, there is a unique lawful and fully parametric implementation of `fmap` with type signature `fmap[A, B]: (A => B) => F[A] => F[B]`

Statement 2: For any fully parametric type constructor F^A contravariant in A, there is a unique lawful and fully parametric implementation of `cmap` with type signature `cmap[A, B]: (B => A) => F[A] => F[B]`

- Note: many typeclasses may admit several lawful, fully parametric, but non-equivalent implementations of a typeclass instance for the same type constructor `F[A]`. For example, `Filterable`, `Monad`, `Applicative` instances are not always unique. But instances are unique for the functor and contrafunctor type classes.

Proof of Statement 1 (uniqueness of functor instances)

For a given functor F, we can construct the "standard" fmap (denoted by $\ldots^{\uparrow F}$) that is involved in the naturality laws

Suppose that there exists *another* lawful and fully parametric implementation $\mathsf{fmap}'(f)$:

$$\mathsf{fmap}' : (A \to B) \to F^A \to F^B \quad , \qquad \mathsf{fmap}'(f^{:A \to B}) = ???^{:F^A \to F^B}$$

We need to show that $\mathsf{fmap}' = \mathsf{fmap}$

By parametricity, fmap' has a naturality law with respect to B:

$$\mathsf{fmap}'(f^{:A \to B} \,\mathring{\,}\, g^{:B \to C}) \overset{!}{=} \mathsf{fmap}'(f) \,\mathring{\,}\, g^{\uparrow F} = \mathsf{fmap}'(f) \,\mathring{\,}\, \mathsf{fmap}\,(g)$$

This suggests using the composition law for fmap':

$$\mathsf{fmap}'(f \,\mathring{\,}\, g) = \mathsf{fmap}'(f) \,\mathring{\,}\, \mathsf{fmap}'(g) \overset{!}{=} \mathsf{fmap}'(f) \,\mathring{\,}\, \mathsf{fmap}\,(g)$$

Since $f^{:A \to B}$ is arbitrary, we may choose $A = B$ and $f = \mathsf{id}^{:B \to B}$ to obtain

$$\underline{\mathsf{fmap}'(\mathsf{id})} \,\mathring{\,}\, \mathsf{fmap}'(g) = \mathsf{fmap}'(g) \overset{!}{=} \underline{\mathsf{fmap}'(\mathsf{id})} \,\mathring{\,}\, \mathsf{fmap}\,(g) = \mathsf{fmap}(g)$$

This must hold for arbitrary $g^{:B \to C}$, which proves that $\mathsf{fmap}'_F = \mathsf{fmap}_F$

Plan for a proof of commutativity law for profunctors

- Main idea: induction on the type expression of a profunctor $P^{X,Y}$
- A fully parametric $P^{X,Y}$ must be a combination of `Unit` type ($\mathbb{1}$), parameters X and Y, products $A \times B$, co-products $A + B$, exponentials $A \to B$, and type recursion (use of P in its definition)
- For each of these cases, we need to show that the commutativity law holds given that it holds for all sub-expressions
    - Base case: show that the law holds for $P^{X,Y} \triangleq \mathbb{1}$ and $P^{X,Y} \triangleq Y$
    - Induction steps: if the law holds for $P^{X,Y}$ and $Q^{X,Y}$, show that it also holds for $P^{X,Y} + Q^{X,Y}$ and $P^{X,Y} \times Q^{X,Y}$ and $P^{Y,X} \to Q^{X,Y}$
    - Show that the law holds for a recursively defined $P^{X,Y} \triangleq S^{X,Y,P^{X,Y}}$ for a type constructor $S^{X,Y,R}$ contravariant in X, covariant in Y and R
    - We need to use the code of functor and contrafunctor instances for products, co-products, function types, and recursive types
- Example: For $R^{X,Y} \triangleq P^{X,Y} \times Q^{X,Y}$, the liftings to R are given by $f^{\uparrow R} \triangleq p \times q \to f^{\uparrow P}(p) \times f^{\uparrow Q}(q)$ and $f^{\downarrow R} \triangleq p \times q \to f^{\downarrow P}(p) \times f^{\downarrow Q}(q)$
    - Write $f^{\downarrow R} \,\mathring{,}\, g^{\uparrow R}$ explicitly using $f^{\downarrow P}$, $f^{\downarrow Q}$, $g^{\uparrow P}$, and $g^{\uparrow Q}$, and show that $f^{\downarrow R} \,\mathring{,}\, g^{\uparrow R} = g^{\uparrow R} \,\mathring{,}\, f^{\downarrow R}$ by assuming that the same law already holds for P and Q

Plan for a proof of parametricity theorem

- Need to prove the naturality law for $t^A : P^{A,A} \to Q^{A,A}$ written as

$$(f^{:A \to B})^{\downarrow P^{\bullet,A}} \, {}_\S^\circ \, t^A \, {}_\S^\circ \, f^{\uparrow Q^{A,\bullet}} = f^{\uparrow P^{B,\bullet}} \, {}_\S^\circ \, t^B \, {}_\S^\circ \, f^{\downarrow Q^{\bullet,B}}$$

- The code of t must be of the form $p \to$ expr, where "expr" must be built up from some of the nine constructions
- Main idea: induction on the code of "expr", assuming that the naturality law holds for all sub-expressions
- Example: induction step for code construction 3 ("create function")
    - The code of t is $p \to z \to r$ and $Q^{X,Y} \triangleq Z^{Y,X} \to R^{X,Y}$
    - Inductive assumption is that any $x \to r$ satisfies the law; let $x = p \times z$
    - Assume that the law holds for $u \triangleq p \times z \to r$, $u : P^{A,A} \times Z^{A,A} \to R^{A,A}$
    - Derive the law for $t = p \to z \to u(p \times z)$ by a direct calculation
- There are some technical difficulties (dinatural transformations do not generally compose) but these difficulties can be overcome with tricks

Summary

- Fully parametric code enables powerful mathematical reasoning:
  - Naturality laws can be used for guaranteed correct refactoring
  - Naturality laws allow us to reduce the number of type parameters
  - In typeclass instances, all naturality laws hold, no need to check
  - Functor, contrafunctor, and profunctor typeclass instances are unique
  - Bifunctors and profunctors obey the commutativity law
- Full details and proofs are in the free upcoming book (Appendix D)
  - Draft of the book: https://github.com/winitzki/sofp
